

Determinatives as nouns in English

Brett Reynolds *

Humber Polytechnic & University of Toronto

Draft, September 2026

Abstract

I argue that English determinatives form a fourth subcategory of Noun, alongside common nouns, proper nouns and pronouns. The argument extends the distributional grounds on which *The Cambridge grammar of the English language* already includes pronouns within Noun despite their distinctive inflection and restricted dependents. Determinatives likewise combine systematic nominal uses with a distinctive internal profile. Comparisons of independent uses, partitives and modification support ordinary nominal headedness while preserving lexical restrictions, including those of articles. An explicit grammatical fragment shows how this analysis extends existing noun-phrase structure and reduces the phrase types admitted in determiner function. Corpus attestations and a reanalysis of published feature data delimit the empirical support. Distributional differences warrant retaining determinative and pronoun as distinct subcategories; they don't by themselves establish a primary-category boundary or decide between coordinate and nested membership within Noun.

Keywords: determinatives, nouns, lexical categories, noun phrases, English

I THE QUESTION

What is the categorial relationship among words such as *some*, *me*, *apple* and *Brett*? I argue that all four are nouns: determinative, pronoun, common noun and proper noun are coordinate subcategories of Noun. In this D-NOUN ANALYSIS, neither determinative nor pronoun is a subcategory of the other.

When offered apples, a speaker can say either *I'll take some apples* or *I'll take some*. The word *some* quantifies over apples in both expressions, but only the first contains a common noun. The D-noun analysis treats *some* as a determinative noun in both uses.

Following *The Cambridge grammar of the English language* (CGEL; Huddleston and Pullum 2002), I use DETERMINATIVE for the category containing articles, demonstratives and quantifiers such as *the*, *this*, *some*, *every* and *many*. I reserve DETERMINER for a syntactic function within the noun phrase. The distinction separates what kind of word *some* is from what its phrase does. Capitalized Noun names the superordinate category when the distinction matters.

*Contact: brett.reynolds@humber.ca

CGEL already places common nouns, proper nouns and pronouns within Noun. It expressly justifies pronoun membership by the functions of pronoun-headed phrases, despite differences in inflection and dependents (Huddleston & Pullum, 2002, pp. 327–328). The question is whether determinatives meet comparable grounds for inclusion. Differences from common nouns alone cannot settle that question: the accepted noun subcategories already differ from one another.

Palmer (1924, p. 24) proposed grouping determinatives with pronouns because most could occur both with and without an accompanying noun; the passage is reproduced in Reynolds (2013, p. 3). The D-noun analysis retains the distinction between those categories within a common superordinate category.

The proposed extension gives independent *some* the phrase structure already needed for other nouns. In determiner function, determinative phrases and genitive NPs share the phrase type NP, while retaining their distinct licensing conditions. The inclusion of auxiliaries within Verb supplies a precedent for this kind of extension: a closed category can retain its distinctive syntax within a broader lexical category (Pullum & Wilson, 1977).

Two comparisons are central: with *CGEL*, which places determinatives outside Noun, and with Hudson's analysis, which places the words he calls determiners within pronoun and pronoun within noun (Hudson, 2004, 2010). Evidence for nounhood alone doesn't decide between coordinate subcategories and Hudson's nesting. Table 1 isolates the structural comparison; Table 2 locates the proposals taxonomically.

To head off a likely misunderstanding: under the D-noun analysis, *apples* still ultimately heads the whole noun phrase *some apples*. Assigning *some* to Noun doesn't adopt the DP hypothesis, in which functional D heads the whole expression (Abney, 1987). The claims concern synchronic English lexical categories.

I first distinguish the competing analyses, then establish what the existing noun subcategories share and how determinatives compare. Independent uses, partitives and modification supply the positive case, with predicative restrictions considered separately. Corpus examples and a reanalysis of published determinative–pronoun data establish the empirical scope. A final grammatical fragment makes the structural gain and its costs explicit.

2 CLASSIFICATION, HEADEDNESS AND FUNCTION

2.1 THREE DECISIONS A GRAMMAR MUST MAKE

Start with *some apples* and independent *some*. In *CGEL*, *some* is a determinative in both. Before *apples*, its phrase functions as determiner. Independently, *some* jointly fills the determiner and head functions: *CGEL* calls this FUSION OF FUNCTIONS (Huddleston & Pullum, 2002, pp. 410–412).

The D-noun analysis retains determinative alongside common noun, proper noun and pronoun within Noun, allowing independent *some* to function as an ordinary head. Table 1 isolates the comparison. Here DP abbreviates determinative phrase, and N_D marks a determinative noun.

The proposal lets independent *some* use ordinary noun-phrase structure. Lexical restrictions remain: *every apple* is grammatical, but **I'll take every* isn't an ordinary way to accept apples. Making *every* a noun doesn't give it every use available to *some*. Section 8.2 states the structural rules and lexical restrictions separately so that their contributions can be assessed.

Category, headedness and function therefore require separate decisions. A category assignment says which lexical generalizations apply to a word. A headedness analysis identifies a phrase's organiz-

Table 1: The same expressions under *CGEL* and the D-noun analysis. Both accounts retain the lexical identity of *some*; they differ in its superordinate category and in the structure assigned to its independent use.

Expression	<i>CGEL</i>	D-noun analysis
<i>some apples</i>	A DP headed by <i>some</i> functions as determiner in the larger NP ultimately headed by <i>apples</i> .	An NP headed by the determinative noun (N_D) <i>some</i> functions as determiner in the larger NP ultimately headed by <i>apples</i> .
<i>some</i> in <i>I'll take some</i>	A DP headed by <i>some</i> functions as fused determiner–head within an NP.	The N_D <i>some</i> fills ordinary head function in a Nom, which heads the NP.

ing head. A function label identifies a constituent's relation to its containing construction. An NP can function as determiner, as in *Kim's book*, and a determinative-headed phrase can have another function, as in *the many people* (Payne et al., 2010; Pullum & Miller, 2022).

For the trees below, a NOMINAL (Nom) contains a head noun and its internal dependents, excluding an external determiner. A lexical noun heads a Nom, which heads an NP; this sequence is NOMINAL PROJECTION, and the noun is the NP's ultimate head. Within *almost every experienced teacher*, *almost every* functions as determiner and *experienced teacher* as head nominal. Within the determiner phrase, *almost* modifies *every*.

I abbreviate noun and determinative as N and D, and determiner and modifier functions as Det and Mod. Det–Head marks fusion. In the proposed trees, NP_D is an NP headed by a determinative noun; the subscript identifies a subcategory. *CGEL*'s DP is a dependent phrase in *some apples*, distinct from the whole expression called DP under the DP hypothesis.

Some earlier proposals concern underlying representation. Postal (1966) unifies personal pronouns and articles through an underlying article analysis. Sommerstein (1972, pp. 197–203) reverses the direction, assigning underlying NP structure to the definite article and personal pronouns, with relative-clause structures contributing further descriptive material. These underlying structures don't by themselves place the surface lexical categories in the hierarchy in Table 2. Déchaine and Wiltschko (2002) further distinguish pro-DP, pro- ϕ P and pro-NP, connecting different pronominal projections with distribution and binding. Their proposal makes the structure associated with a pronoun an additional question for comparison.

J. Lyons (1968, pp. 232–235) supplies a useful methodological distinction: distribution can be compared at different levels of categorization. Two expressions may belong together at one level and differ at a more specific level. His discussion of articles, demonstratives and personal pronouns also emphasizes shared definiteness and deictic contrasts (J. Lyons, 1968, p. 279).

Bruening (2020) supplies a generative defence of N-headed nominals, drawing on selection and conventionalized expressions. Such arguments support N-headed phrase structure without by themselves assigning determinatives to the noun category.

Table 2: Selected taxonomic arrangements. Noun contains common and proper nouns in every row; its other members vary. Logical comparisons locate the cited proposals. The Hudson row abstracts from differences in lexical inventory explained in the text.

Relation among Noun, pronoun and determinative	Account or status
Noun, pronoun and determinative are separate primary categories.	Logical comparison
Pronoun is within Noun; determinative is a separate primary category.	<i>CGEL</i>
Determinative is within Noun; pronoun is a separate primary category.	Logical comparison
Pronoun and determinative are coordinate subcategories of Noun.	D-noun analysis
Determinatives belong within pronoun, which is within Noun.	Hudson
Pronoun is within determinative, which is within Noun.	Reverse nesting for comparison

2.2 THE NEAREST ALTERNATIVES

Keeping a word in one category across dependent and independent uses leaves its taxonomic position open. Table 2 sets out selected arrangements, from three separate primary categories to successive inclusion. Common and proper nouns remain within noun throughout the comparison. The D-noun analysis differs from *CGEL* by including determinative within Noun, and from Hudson by placing it alongside pronoun.

Anderson (1997) groups names, pronouns and determining words as a notional {N} category, with common nouns represented separately. His {N} differs from the inclusive Noun proposed here and isn't one of the arrangements in Table 2.

Hudson's nominal analysis makes a different choice. In Hudson (2010, pp. 253–254), noun has the subcategories common noun, proper noun and pronoun. Hudson identifies the words he calls determiners by *VALENCY*: the kinds of dependent an item permits. In Hudson's terminology, a determiner is a pronoun that permits the relevant common-noun dependent (Hudson, 2004, pp. 9–10). Identifying these words doesn't require another category node.

CGEL and Hudson classify different inventories. Hudson's criteria in the 2004 paper centre on licensing a singular count common noun and on mutual exclusion in that use. He sets aside *all*, cardinal numerals and quantifiers restricted to plural or non-count nouns. *CGEL*'s determinative category is broader. Comparing the classifications therefore requires checking which words and constructions each covers.

Hudson also separates dependency from phrase headedness. His 2004 account permits mutual dependency between determiner and common noun, with different constructions selecting different external heads (Hudson, 2004, pp. 7–9). Temporal adjuncts provide an illustration: *We met that day* depends on the temporal meaning of *day*. Such restrictions support a common-noun head for temporal adjuncts (Hudson, 2004, pp. 10–12).

The alternative to a separate primary D needn't preserve a unified determinative subcategory. Spinillo (2004) proposes redistribution among existing categories, retaining *the*, *a* and *every* as an expanded article category. That proposal makes the restricted members a separate category; the D-noun analysis retains them inside the wider determinative subcategory.

For demonstratives and forms such as *some* and *all*, Spinillo (2004, pp. 140–144) rejects switching between determiner and pronoun categories according to whether a noun follows. She compares the alternation with verbs and prepositions used with or without a complement. The D-noun analysis agrees that the two uses needn't involve different lexical categories. It differs in retaining determinative as the subcategory across those uses.

Independent nominal use supports inclusion within Noun, but doesn't itself select the pronoun subcategory. The demonstratives' deictic properties make a pronominal grouping plausible; the question is how far that grouping captures the wider inventory's syntax. The comparisons below address modifier profiles (§3.5), the proposed determinative–pronoun boundary (§6), and the positive connections linking restricted *every* to other quantifiers (§7). Redistribution must be assessed against those connections as well as independence.

Van Eynde (2003) likewise rejects a separate determiner category, but assigns determining expressions to adjective or noun on morphological and agreement evidence, chiefly from Italian and Dutch. His analysis separates lexical category from the features governing determination. A noun-headed NP account therefore needn't unify every determining expression as nominal.

3 THE D-NOUN ANALYSIS

3.1 THE EXISTING STANDARD OF NOUNHOOD

The starting category is Noun as *CGEL* already constitutes it. Its discussion of pronouns makes the reasoning explicit: they differ from prototypical nouns in inflection and permitted dependents, but qualify through heading phrases with the functions of common- and proper-noun-headed phrases (Huddleston & Pullum, 2002, p. 327). Table 3 sets out some of the variation already accepted within that category.

Table 3: Contrasts already accommodated within *CGEL*'s Noun. These are typical profiles, with further restrictions and exceptions within each subcategory (Huddleston & Pullum, 2002, pp. 327–328, 425–430, 517–520).

Dimension	Common noun	Proper noun	Pronoun
Inventory	Open	Open to new names	Closed
Inflection	Number and genitive	Genitive; restricted plural uses	Case paradigms in personal pronouns
Determination	Broad contrasts; singular count arguments normally require it	Restricted in primary naming uses	Normally excluded
Internal modification	Productive AdjP and nominal modification	Restricted embellishments	Restricted, as in <i>poor old me</i>

Common nouns supply the most familiar profile, but they don't supply an entry test that every noun subcategory has to pass unchanged. Pronouns remain nouns despite their closed inventory and restricted modification; proper nouns remain nouns despite their distinct naming uses. An argument that excludes determinatives on these kinds of difference therefore needs to explain why the difference warrants a primary-category boundary in this case.

Meaning and reference also vary within the existing category. *Apple* conveys a descriptive classification; *Kim*, in its primary naming use, identifies through a name; *she* supplies limited descriptive content and depends on context. Noun already accommodates those differences. The quantificational or deictic contribution of a determinative therefore needs to be assessed alongside its grammar, rather than measured against common-noun semantics alone.

The positive distributional test follows the same starting point as *CGEL*'s pronoun argument. Can a range of determinatives head phrases in subject, object and complement-of-preposition positions without another overt nominal head? The pattern should recur across lexemes and appropriate discourse contexts. This tests systematic nominal use before assigning its internal structure. The examples in §4 compare all four proposed subcategories in the same positions.

External distribution alone is insufficient: adjectival constructions such as *the rich* also fill those positions. The further comparison concerns the breadth of independent use, determination, partitives and internal modification. Together these properties support a nominal subcategory profile. Restrictions on particular lexemes or readings remain part of the description, just as they do within the existing Noun category; §§4.6 and 7 examine them directly.

The distinction at issue is thus one of taxonomic level. A closed inventory, reduced descriptive content or unusual modifier selection can establish a distinctive subcategory without establishing its exclusion from Noun. The decisive comparison is whether the shared nominal behaviour and the local differences are better captured by extending existing nominal structure or by preserving a separate primary D. Section 8.2 holds the lexical restrictions fixed to make that comparison explicit.

By INHERITANCE I mean that a property stated for a superordinate category is available to its subcategories, subject to stated restrictions. The D-noun analysis extends the division of labour already used within Noun: general rules supply nominal projection, subcategory rules constrain combinatorics, and lexical entries distinguish such forms as independent *some* and dependent-only *every*.

3.2 NOUNS ALREADY FUNCTION AS DETERMINERS

Determiner function also cuts across the existing noun subcategories. Compare *my book*, *Kim's book* and *the king's book*. The determiner is an NP ultimately headed by a pronoun, a proper noun and a common noun respectively (Huddleston & Pullum, 2002, pp. 354–355, 470–471). In the last example, *the* determines *king* inside the genitive NP, while that whole NP determines *book*.

These expressions establish more than the possibility of a noun in Det function. All three admitted noun subcategories already contribute phrases to that function, subject to the genitive construction's restrictions. The D-noun analysis extends this nominal pattern to determinative-headed phrases. Number, countability and other selectional conditions still distinguish the determining expressions; their shared function doesn't imply unrestricted interchangeability.

Figure 1 illustrates the proper-noun case. The genitive NP *Kim's* functions as Det, while *book* ultimately heads the larger NP. This existing configuration provides the comparison for the determinative analysis that follows.

Figure 1: The genitive NP *Kim's* functions as determiner within *Kim's book*, ultimately headed by *book*. The representation abstracts from the internal realization of genitive marking.

3.3 DEPENDENT AND INDEPENDENT USES

Figure 2 gives the proposed analyses of *some apples* and independent *some*. Function labels appear above category labels. In the first tree, the inner NP_D functions as Det within an NP ultimately headed by the common noun *apples*. In the second, the determinative noun *some* supplies the lexical head of the object NP. The lexeme has the same subcategory in both trees; its containing phrase has a different function.

The NP headed by *some* inside *some apples* isn't interchangeable with every NP. The determiner construction selects a determinative-headed phrase, a suitable genitive NP, or another licensed expression. Section 8 includes this restriction in the comparison of grammars.

3.4 TWO HEADS IN ONE EXPRESSION

Figure 3 separates the two modifier relations in *almost every experienced teacher*. The AdvP *almost* modifies the determinative noun *every*; the AdjP *experienced* modifies the common noun *teacher*, which ultimately heads the outer NP.

3.5 WHAT THE MODIFIER CONTRAST ESTABLISHES

Payne et al. (2010, pp. 40–42) defend keeping *few*, *any* and related forms in one lexical category across dependent and independent uses. The modifier remains an adverb in *hardly any money/hardly any*; changing the item's function doesn't require changing its category. The D-noun analysis preserves that continuity. It also preserves their contrast between adverbial premodification, as in *almost anybody*, and adjectival postmodification, as in *nothing absolute*.

These contrasts support distinguishing determinatives from pronouns and common nouns. The further question is the taxonomic level of that distinction. Within the proposed Noun, the determinative subcategory licenses *hardly any* and *almost every*; the common-noun subcategory licenses *experienced teacher*. Neither **experienced every* nor **almost teacher* follows. The existing modifier profiles remain, while their relation to the broader category changes. Section 8.3 considers the cost of that change explicitly.

Figure 2: The proposed analyses of *some apples* (left) and independent *some* (right). Follow the N_D –Nom–NP sequence above *some*: it is shared across uses. The resulting phrase functions as Det on the left and as the object in *I’ll take some* on the right.

Payne et al. (2010, pp. 60–61) also argue that distribution alone can’t decide whether adjectives and adverbs are inflectional variants of one category or derivationally related members of different categories. The D-noun analysis preserves distinct lexical subcategories and makes no inflectional-variant claim. Their methodological constraint still applies: shared positions alone don’t settle category status. Here the fuller constructional profile is assessed against the grounds on which *CGEL* already includes divergent subclasses within Noun.

4 EVIDENCE FOR NOMINAL STRUCTURE

The comparison concerns three properties: the breadth of independent use across the determinative inventory, structural saturation without another overt head, and internal modification. Partitives help identify which expression heads the larger construction.

4.1 BREADTH OF INDEPENDENT USE

Independent use is widespread within the determinative inventory. *CGEL* discusses such uses for demonstratives and quantifiers including *some*, *all*, *both*, *many*, *few*, *several*, *each*, *either*, *neither*, *much* and *enough*, while recording lexical restrictions and the separate forms *no/none* (Huddleston & Pullum, 2002, pp. 371–372, 410–424). The generalization is about the availability of constructions across a lexical category, not the unrestricted acceptability of every member in every sentence frame.

In the constructed examples in (1), compare the positions occupied by the bracketed NPs: subject, object and complement of a preposition. Assume that a woman named Kim and a group of people are already under discussion. These positions admit NPs containing words from each proposed noun subcategory; the competing analyses assign different internal structures to independent *some*.

Figure 3: Two modifier relations in *almost every experienced teacher*: *almost* modifies *every*, and *experienced* modifies *teacher*. The outer NP has *teacher* as its ultimate head. Internal structure within the one-word modifier phrases is suppressed.

- (1) a. *[People] left.* *I see [people].* *with [people]*
 b. *[Kim] left.* *I see [Kim].* *with [Kim]*
 c. *[She] left.* *I see [her].* *with [her]*
 d. *[Some] left.* *I see [some].* *with [some]*

The pattern extends beyond a few compounds or a single lexicalized expression. For this closed category, PRODUCTIVITY concerns the availability of independent use among established members under appropriate conditions, rather than the licensing of new lexical items.

Adjectival independent uses prevent a simple inference from external distribution to nounhood. *The rich* and *the poor* can fill nominal argument positions. Comparative and superlative adjectives also head expressions without a human-class interpretation: *CGEL's the most important of her criticisms* is an NP containing a partitive *of*-phrase (Huddleston & Pullum, 2002, pp. 332–333, 416–423).

Independent *some* can form a one-word NP, whereas an NP with *rich* as fused head normally requires a determiner on the human-class reading. That is a local contrast: argument NPs headed by singular count common nouns also need determination.

4.2 STRUCTURAL SATURATION AND INTERPRETATION

With a group of people under discussion, *Some left*, *Many came* and *All agree* illustrate STRUCTURAL SATURATION: an argument expression can be syntactically complete without another overt head or determiner.

Syntactic completeness differs from contextual interpretation. In *I'll take some*, the relevant substance or set may be supplied by discourse or the situation. That dependence doesn't establish a deleted common noun: ordinary pronouns also depend on context.

The comparison with ordinary pronouns and proper nouns is structural as well as interpretive. In *She left* and *Kim left*, *CGEL* permits an NP headed by a nominal with no determiner. Applying that structure to *Some left* preserves the same division between a complete NP and its context-dependent

Figure 4: The proposed structure of *some of the wine*. Follow the Head relations from the outer NP to *some*. The common noun *wine* is inside the modifying PP and doesn't head the whole expression.

reference. The dependent use of *some* doesn't by itself require a Det function inside every independent occurrence.

Nounhood also remains compatible with fusion. *CGEL* analyses *mine* as fused Det–Head when it stands for a possessed entity in an anaphoric context, but as pure Head in the predicative possessive use *it's mine* (Huddleston & Pullum, 2002, pp. 410–411). That comparison blocks an objection from fusion to nounhood. The positive case for ordinary headedness instead extends the structure available to *she* and *Kim*.

Generalizing expressions such as *Many are called*, *few are chosen* and *Enough is enough* need no previously uttered common-noun phrase. They rule out a mandatory overt-antecedent requirement, but a silent-noun account could supply a generic restriction. Such examples don't decide whether the restriction belongs in semantics or syntax.

Saturation thus establishes the availability of complete argument expressions without an overt determiner or common noun. The preference for ordinary headedness comes from combining this fact with the established noun comparison and the internal structures below. It doesn't depend on treating the absence of an overt antecedent as proof against every silent-noun account.

4.3 PARTITIVES LOCATE THE QUANTIFICATIONAL HEAD

In *some of the wine*, *some* specifies a quantity drawn from an identifiable amount of wine. The NP *the wine* denotes the partitive DOMAIN: the whole from which that quantity is drawn. This NP is complement of *of*. A pronoun-headed NP or independent genitive NP can express the domain too: *many of them*, referring to previously mentioned people, or *some of Kim's*, referring to Kim's apples.

Compare where the common noun occurs in *some apples* and *some of the wine*. In the partitive, *wine* is embedded inside the *of*-phrase, so it can't be the lexical head of the whole NP. The determinative *some* has an organizing role in that larger expression.

Figure 4 gives the D-noun analysis, with the *of*-phrase functioning as a post-head modifier, following *CGEL* (Huddleston & Pullum, 2002, p. 411). The inner NP *the wine* is abbreviated.

CGEL accounts for these facts through Det–Head fusion. Partitives support the determinative's head-like role, while leaving the choice between fusion and ordinary headedness open.

Figure 5: The proposed structure of *the lucky few*. Determiner and head are separately realized: *the* determines a nominal headed by *few* and modified by *lucky*. Internal structure within the article phrase and AdjP is suppressed.

The D-noun analysis treats *some* and *some of the wine* as sharing nominal projection, with an added domain phrase in the partitive. Modification provides a further comparison of internal structure.

4.4 MODIFICATION TESTS THE INTERNAL ANALYSIS

The pair *the lucky survivors/the lucky few* makes the case for ordinary nominal structure particularly visible. In the D-noun analysis of the second expression, *the* determines a Nom containing the modifier *lucky* and the head *few* (Figure 5). The overt determiner and the overt quantificational head fill separate functions.

The constructed examples *the remaining three* and *the selected two* broaden the comparison beyond *few*. On the intended readings, the expressions denote the people remaining or selected, and the cardinal specifies their number. The modifier occurs between the article and the quantificational head, as in *the lucky few*. This pattern therefore calls for an account extending beyond one lexical item.

The ordinary-Head analysis gives these expressions the same Det–Nom organization as *the lucky survivors*, with an overt lexical head in each. A silent-noun analysis introduces another head; a conversion analysis assigns a common-noun use to the quantifier or cardinal. Those alternatives need a benefit that offsets the additional structure or category assignment. In the displayed constructions, the D-noun analysis captures the overt modifier–head pattern while preserving the quantificational item’s subcategory.

The modifiers in *hardly any* and *almost every* are adverbs; corresponding attributive adjectives aren’t licensed. The pattern in *the lucky few* is likewise restricted. The D-noun analysis retains these lexical differences.

Nor is adjectival premodification exclusive to determinatives: *the idle rich* has an adjectival fused head. Internal modification distinguishes particular constructions, rather than providing a categorical nounhood test.

The contribution of modification is consequently structural. It supplies positive parallels with ordinary nominal organization and broadens the lexical coverage of that comparison. The argument for a noun subcategory combines these parallels with independent distribution; it doesn’t require every determinative to permit adjectival modification.

4.5 WHAT REMAINS OF FUSION

Payne et al. (2007) characterizes fusion through six properties. One constituent fills two adjacent functions: head and a dependent function of the same phrase or of an immediate dependent. The fused constituent typically differs in category from its containing phrase. Two further properties connect fusion to a non-fused counterpart: the containing phrase projects from the counterpart's head category, and the fused constituent has the counterpart's dependent category. In *some apples/some*, NP is the containing category and D is the category of the dependent or fused constituent.

In the ordinary-Head variant, independent *some* fills Head alone. Locality and adjacency consequently have no two-function relation to constrain. Projection rules supply the N–Nom–NP sequence. The word *some* retains its lexical identity across dependent and independent uses, while its phrases fill different functions.

Payne et al. (2007) also explicitly ties the exclusion of independent *every* and the form *none* to lexical differences in fusion licensing. The D-noun analysis still needs those differences, now stated as permissions for independent use and form selection. Section 8.2 holds those permissions fixed when comparing the structures.

Adjectival fusion is retained. In *the rich*, *rich* remains adjectival and realizes fused Mod–Head within Nom; the article-headed phrase fills Det. In *the idle rich*, *idle* modifies that nominal. The broader independent distribution of determinatives motivates ordinary nominal projection for that category, while the restricted adjectival constructions retain their separate analysis.

Compounds require further description. For *hardly anyone present*, Payne et al. (2007) uses determinative-phrase structure to license the pre-head adverb and NP structure to license the post-head adjective. An ordinary-Head analysis needs subcategory and constructional restrictions to preserve this contrast inside Noun. The rules in §8.2 cover simple determinatives; they don't complete the analysis of compounds.

4.6 PREDICATIVE USES AND THEIR RESTRICTIONS

Predicative complementation provides a less uniform comparison. *CGEL* records *Its advantages are several* and *Their enemies were many*, describing the latter pattern as uncommon and formal (Huddleston & Pullum, 2002, pp. 392, 395–396). Such uses are available to only part of the determinative inventory. The ordinary independent uses of *some* therefore cannot license every determinative in every predicative frame; *every* and the articles retain their restrictions.

The comparison also depends on what the predication expresses. *She is a doctor* ascribes a property, whereas *That is Kim* identifies a person. *CGEL* excludes specifying *be* clauses from its noun–adjective diagnostic because phrases from other categories occur in them too (Huddleston & Pullum, 2002, p. 536). Merely placing an expression after *be* therefore provides no uniform nounhood test.

Restrictions in the opposite direction already occur within nominal grammar. A bare-role NP such as *president* is licensed in *I'd like to be president*, but requires determination in the corresponding object use *I'd like to meet the president* (Huddleston & Pullum, 2002, p. 328). Predicative and argument uses thus need separate conditions within Noun itself. The determinative asymmetries belong in that comparison; they don't establish exclusion merely by departing from a common-noun substitution frame.

4.7 THE CUMULATIVE CASE FOR ORDINARY HEADEDNESS

The comparisons favour ordinary headedness for the simple independent cases. First, nominal argument use recurs across the determinative inventory, so it calls for a category-level account. Second, those expressions are complete without an overt common noun, like ordinary pronoun- and proper-noun-headed NPs. Third, partitives and internally modified expressions locate an overt quantificational head in structures that can share ordinary nominal organization. The modifier and predicative restrictions specify the resulting subcategory's profile.

I take this combined pattern to support extending the existing Noun category. *CGEL* already admits pronouns through shared nominal functions despite distinct inflection and dependents. Determinatives supply a further instance of that relation between common external behaviour and specific internal restrictions. On the D-noun analysis, the ordinary Head relation follows the same nominal sequence across all four subcategories, and lexical identity is preserved across dependent and independent uses.

Fusion can describe the same independent cases, and it remains needed elsewhere. The comparative advantage here is that a widespread use receives the structure already available for other nouns, with the restrictions retained. A separate-D account would earn its additional distinction by capturing a generalization lost under the extension, or by giving the constructions a better analysis. Section 8.2 identifies what changes when the alternatives receive the same lexical permissions.

5 WHAT THE EMPIRICAL RECORD ESTABLISHES

5.1 A REPRODUCIBLE CORPUS INVENTORY

CGELBank is a corpus of English sentences annotated using categories and functions developed from *CGEL* (Reynolds et al., 2023). It supplies inspectable examples with stable sentence identifiers. Its category and fusion labels already encode analytical decisions, so label counts can't independently establish that *CGEL* or the proposed replacement is correct.

I inventory four CGELBank datasets containing 220 sentence trees and 3,390 lexical nodes with overt text. Of those nodes, 387 are annotated D. Table 4 compares selected forms by their local function. These are counts of annotated uses, not estimates of a lexeme's capacity for independent use. Appendix A gives the source revision, selection criteria and extraction procedure; an accompanying concordance preserves the sentences and their identifiers.

The sample has no determinative tokens of bare *few*, *either* or *neither*. For these forms, the breadth claim in §4 rests on *CGEL*'s grammatical descriptions and judgments; this corpus sample supplies no confirming attestations.

All 65 Det–Head occurrences were inspected in their source sentences. They include ordinary arguments, partitives, compounds such as *something*, floating quantifiers, degree and frequency expressions, numerical fragments and age supplements. Within *about 30 seconds*, for example, the numeral's nominal projection is embedded in the determiner *about 30*. Reporting all 65 occurrences as independent argument uses would conflate different constructions.

Two attestations illustrate independent quantifiers with a recoverable domain:

- (2) a. *Went there yesterday: we are trying to decide between two different Honda models, so we wanted to test-drive both back to back.*
- b. *I rarely listen to the news or to what politicians or lawyers say because so many tell lies that none have credibility so what's the point?*

Table 4: Selected forms by local function in CGELBank. Compare forms attested in both Det and Det–Head uses with forms restricted to Det in this sample. Other includes all remaining functions. Counts group forms by corpus lemma, including singular and plural demonstratives.

Form	Total	Det	Det–Head	Other
<i>the</i>	129	129	0	0
<i>a</i>	90	89	0	1
<i>every</i>	3	3	0	0
<i>this</i>	28	21	7	0
<i>that</i>	12	5	7	0
<i>some</i>	5	3	2	0
<i>all</i>	11	3	5	3
<i>both</i>	4	2	1	1
<i>many</i>	3	0	1	2
<i>a few</i>	2	1	1	0
<i>each</i>	2	0	1	1
<i>enough</i>	6	2	1	3

In (a), *both* refers to the two Honda models. In (b), *politicians or lawyers* supplies a domain for *many* and *none*. These attestations illustrate independent quantifiers whose interpretation is supplied by preceding discourse. Appendix A identifies the source sentences.

CGELBank also attests *I need something reliable and good looking*; the concordance gives the sentence identifier. The adjectives follow the compound determinative *something*, contrasting with the premodification in *the lucky few*.

The inventory attests independent and internally expanded determinatives, but provides no representative productivity estimate or controlled test of the modifier contrasts. The constructed examples in §4 remain grammatical judgments.

5.2 WHAT DISTRIBUTIONAL DIFFERENCES ESTABLISH

Do determinatives and pronouns differ too much to belong to the same broader category? Reynolds (2021b) compared 73 determinative forms and 65 pronoun forms using a binary feature matrix: each row is a form, and each column records a morphological, phonological, semantic or syntactic property. The matrix contains no common or proper nouns, so it can establish differences between the two supplied categories but can't test nounhood directly.

Two statistical methods answer different questions. DISCO tests separation between preassigned groups; k-groups searches for two clusters without using category labels. The DISCO tests confirm separation across several feature selections. The clustering is less stable: with the public matrix, agreement with CGEL's classification ranges from 75 to 132 of 138 forms across random starts. The original report of 129 matches is attainable, but depends on initialization. Agreement also changes with feature selection.

Differences between coded profiles don't determine taxonomic rank: subcategories of one category can differ sharply. The reanalysis supports distributional separation between the determinative and pronoun forms in this inventory, while leaving their classification within Noun open. Reyn-

olds's original discussion likewise recognized significant divisions within categories and left a nested nominal analysis open (Reynolds, 2021b).

Appendix A gives the methods and sensitivity results, including a discrepancy between the reported 232 features and the 155 in the public file (Reynolds, 2021a). The comparisons are exploratory; agreement with *CGEL*'s labels isn't accuracy against an independent ground truth.

6 COORDINATE SUBCATEGORIES AND INHERITANCE

Should determinatives and pronouns be coordinate subcategories, or should determinatives belong inside pronoun? The matrix reanalysis leaves that choice open. Its pronoun rows follow *CGEL*'s classification, whereas Hudson's pronoun category includes the words he calls determiners. Comparing these hierarchies requires aligning their lexical inventories and asking which generalizations can be stated for each superordinate category.

The case for coordinate subcategories starts from the different concentrations of grammatical properties. Core personal pronouns have case contrasts, reflexive forms and person distinctions. Determinatives organize contrasts in quantification, determination and degree modification. These descriptions allow exceptions and further subtypes; their role is to preserve the local grammatical distinctions within a shared nominal architecture.

Within the proposed grammar, nominal projection rules apply to all four subcategories, so they can be stated for Noun as a whole. An intermediate pronoun-plus-determinative category would need to capture additional generalizations. Reduced descriptive content and contextual interpretation are properties shared by many pronouns and determinatives. The coordinate analysis can record these interpretive properties through features or cross-classification; Hudson's nested classification may be preferable if it collects several otherwise repeated generalizations.

Restricted determination and attributive modification provide an immediate candidate for an intermediate category. Pronouns normally reject determiners and pre-head internal dependents, with exceptions such as *poor old me* (Huddleston & Pullum, 2002, pp. 429–430). But the restrictions don't coincide across the proposed pronoun–determinative grouping: *the lucky few* permits both an external determiner and an attributive adjective.

Proper names also differ from common nouns in these respects. In their primary use, they don't select freely from the determiner system, and their adjectival embellishments are restricted (Huddleston & Pullum, 2002, pp. 517, 519–520). A default restriction for Hudson's broader pronoun category remains possible, but it would need exceptions within that category and related restrictions outside it. Its descriptive advantage requires comparison with these cross-cutting patterns.

Pro-form gender supplies a further comparison. Reynolds (2025) proposes a personhood-based system spanning pronouns and determinatives. Personal reference links pronouns such as *she* with compound determinatives such as *somebody*; non-personal reference links *it* with *something*. These constraints concern how the referent is construed. They provide a shared generalization for nominal pro-forms, but don't decide between coordinate and nested noun subcategories. The broader pro-form system also includes non-nominal expressions, so gender alone doesn't delimit Noun.

The coordinate classification preserves *CGEL*'s determinative/pronoun distinction while extending nominal structure across its inventory. Evidence favouring Hudson would be an additional syntactic generalization covering the aligned pronoun-plus-determinative inventory, excluding common and proper nouns, and reducing otherwise repeated restrictions. A shared semantic feature alone

doesn't require an intermediate category. Section 8.2 checks the two hierarchies over a limited grammatical fragment.

7 THE ARTICLES AND OTHER RESTRICTED MEMBERS

Why classify the articles *the* and *a* as nouns if they can't stand independently? Independent uses motivate the D-noun analysis of *some*, *this* and *many*, but the articles require a different argument. *Every* is restricted too, while *no* has the distinct independent form *none* (Huddleston & Pullum, 2002, pp. 371–372, 410–411).

Retaining a restricted member requires three kinds of support. First, it should be paradigmatically integrated with independently identified members. Second, it should participate in the category's characteristic semantic and grammatical contrasts. Third, its missing uses should form a local restriction while the positive connections remain. Calling an item DEFECTIVE summarizes that pattern; it doesn't supply an argument for membership by itself.

The articles meet these conditions within determinative. First, they contrast with demonstratives and quantifiers before common-noun nominals: *the/a/this/every book*. Second, they participate in the same system of definiteness, number and count restrictions: *the* permits singular, plural and non-count targets, while *a* selects a singular count target. Third, their lack of ordinary independent uses leaves that determining pattern intact. These considerations support determinative membership; inclusion within Noun depends on the category-level argument.

Restricted members already occur within Noun. *CGEL* classifies *my* as a pronoun despite its lack of the independent distribution of *mine* (Huddleston & Pullum, 2002, pp. 470–471). Under the proposal, an NP headed by an article is likewise licensed as a determiner but excluded from ordinary argument use; §8.2 states that restriction explicitly. The comparison concerns a missing use within a noun subcategory.

Every also has positive connections beyond the restricted article set proposed by Spinillo (2004). Like *each*, it expresses universal quantification and selects singular count nominals: *every teacher, each teacher*. Unlike *each*, it lacks ordinary independent use. It also permits *almost* and *nearly*. These facts support retaining *every* with the quantifiers without making its full distribution identical to that of *each*.

Grammaticalization supplies background to such restrictions. C. Lyons (1999, pp. 331–336) discusses the development of definite articles from demonstratives and of articles expressing cardinality from numeral sources. These histories can illuminate changes in semantic content and use. They don't establish a synchronic category or make historical reduction a condition of defective membership. A separate article category would remain preferable if it captured a substantial set of otherwise exceptional synchronic restrictions.

8 WHAT THE ANALYSIS SIMPLIFIES

8.1 A SHARED PHRASE TYPE IN DETERMINER FUNCTION

In *some apples* and *Kim's apples*, the phrases headed by *some* and *Kim* fill the same determiner function. *CGEL* assigns them different phrase types, DP and genitive NP. It also admits a restricted range of plain-case NPs and PPs as determiners, as in *what size hat* and *over thirty ties* (Huddleston & Pul-

Table 5: Shared permissions in the fragment. For *some*, the target column concerns its unstressed use before a noun. The inventory is deliberately limited to the displayed constructions.

Form	Det use	Argument use	Target in the Det construction
<i>the</i>	yes	no	Singular or plural; count or non-count
<i>a, every</i>	yes	no	Singular count nominal
<i>some</i>	yes	yes	Plural count or non-count nominal
<i>few</i>	yes	yes	Plural count nominal
<i>my</i>	yes	no	No number/count restriction in this fragment
<i>she</i>	no	yes	None

lum, 2002, Ch. 5, §4). The D-noun analysis reduces this phrase-type inventory:

$$\begin{aligned} \text{CGEL: } \text{Det} &: \{\text{DP}, \text{NP}, \text{PP}\} \\ \text{D-noun analysis: } \text{Det} &: \{\text{NP}, \text{PP}\} \end{aligned}$$

The gain is one shared nominal projection for the determinative and genitive cases. Selection still distinguishes determinative-headed, genitive and other licensed NPs; PP determiners remain. Nor does reclassification derive definiteness or the single-Det restriction: *CGEL* already states their common determining behaviour functionally. Independent *some* and *Kim's* are already NPs in both accounts. Giving *some* ordinary headedness is a further change, assessed separately below; genitive fusion remains available.

8.2 A MATCHED DESCRIPTIVE FRAGMENT

A grammatical **FRAGMENT** is a set of rules for a specified range of constructions. Here the range includes determination, ordinary subject and object uses, partitives, and the modifier contrasts in §4. I compare *CGEL*'s separate-D analysis with two nominal variants: one retaining fusion, the other using ordinary headedness. All three receive the same lexical restrictions and constructed judgments, allowing category membership and headedness to be varied separately. The separate predicative constructions discussed in §4.6 fall outside this fragment.

Table 5 records **USE PERMISSIONS**: whether a form, on a given reading, can head a phrase in determiner, subject or object function. **ARGUMENT USE** covers the subject and object NPs in examples such as *Some left* and *I saw some*. Quotation, metalinguistic naming and subordinate-clause uses of dependent genitives fall outside the fragment. Noun membership doesn't itself grant a use permission.

Further constructional restrictions apply: *she* is a subject form, whereas the corresponding ordinary object form is *her*. The target restrictions in Table 5 concern the common-noun nominal being determined. For example, *a* requires a singular count target such as *book* in *a book*.

The ordinary-Head variant has three rules. In the schema below, *h* identifies the lexical head throughout its projection; parentheses mark optional dependents within this fragment. The subscripts on *Mod* distinguish pre-head and post-head positions of the same modifier function. The

head's entry and construction restrict every dependent.

$$\begin{aligned} \text{Nom}_h &\rightarrow (\text{Mod}_{\text{pre}}) \quad \text{Head} : \text{N}_h \quad (\text{Comp}) \quad (\text{Mod}_{\text{post}}) \\ \text{NP}_h &\rightarrow (\text{Det}) \quad \text{Head} : \text{Nom}_h \\ \text{licensed}(\text{NP}_h, f, c) &\iff f \in U_h \wedge C_h(f, c) \end{aligned}$$

Here U_h is the head's set of use permissions, f is the NP's function, and C_h checks the lexical and constructional conditions in context c . For Det use, these include compatibility with the target nominal; for an argument headed by a singular count common noun, they include required determination. Optionality in the second rule doesn't override those conditions.

Each NP's use permissions follow its own head. In *the apple*, the article's Det permission licenses the dependent NP headed by *the*. The outer NP takes its argument permission from *apple*, whose requirement for determination is satisfied by the article.

In *some apples*, *some* heads an NP whose Det permission and plural-count target requirement are satisfied. *Apples* heads the outer Nom, which heads the NP. In *Some left*, *some* heads an NP whose argument permission is satisfied. *Every apple* passes the Det and singular-count checks; ordinary independent **Every left* fails the argument-permission check. *The apple* and **The left*, with *left* as a verb, differ in the same way.

A singular count common noun such as *book* faces a different restriction. In *a book*, its requirement for determination is satisfied; bare **Book arrived* leaves that requirement unsatisfied. *Books arrived* has no such requirement. Requiring determination for a common noun doesn't itself block an article-headed NP from argument use. An article's exclusion from argument use must still be stated separately.

Partitives and modifiers require further lexical conditions. *Some* and *few* permit a partitive *of*-phrase within their nominal projection. *Almost* can modify *every* in *almost every teacher*; that permission doesn't license *experienced* as a modifier of *every*. The construction *the lucky few* permits the external determiner and adjectival modifier shown in Figure 5. None of these permissions transfers automatically to every determinative noun.

The separate-D grammar already needs nominal projection for common nouns, proper nouns and pronouns. For the determinative constructions it additionally needs a DP projection and a route from that projection to independent NP use. Abstracting from the same lexical conditions, those two schemata are:

$$\begin{aligned} \text{DP}_h &\rightarrow (\text{Mod}_{\text{pre}}) \quad \text{Head} : \text{D}_h \quad (\text{Comp}) \\ \text{NP}_h &\rightarrow \text{Det-Head} : \text{DP}_h \quad (\text{Mod}_{\text{post}}) \end{aligned}$$

The first supplies phrases such as *almost every*; the second gives independent *some* its containing NP through fusion. In the ordinary-Head variant, the existing Nom and NP schemata cover these determinatives, with their lexical permissions unchanged. The partitive PP remains a post-head modifier: beside the fused head in NP in these schemata, and inside Nom in the ordinary-Head analysis.

Hold these lexical and constructional restrictions fixed and vary the analysis. In CGEL's separate-D account, dependent uses project a DP, while independent uses such as *some* receive NP distribution through Det-Head fusion. In the nominal variant retaining fusion, D becomes a noun subcategory but independent constructions keep their fused function. In the ordinary-Head variant, independent determinatives follow the N-Nom-NP sequence. Table 6 separates the changes.

Table 6: Taxonomy and ordinary headedness varied separately over the same fragment. All three descriptions retain the permissions in Table 5 and the modifier restrictions.

Account	Primary taxonomy	Simple independent determinative
Separate D, fusion	D outside Noun	NP distribution through Det–Head
Nominal D, fusion	D inside Noun	NP distribution through Det–Head
Nominal D, ordinary Head	D inside Noun	N–Nom–NP projection with Head function

Moving D inside Noun removes a primary-category boundary. Replacing fusion with ordinary headedness lets simple independent determinatives share an existing projection and Head relation. Fusion remains available for adjectival and genitive constructions. The gain is structural, with lexical restrictions retained.

A separate-D grammar could instead license D-headed NPs directly, through a rule permitting either N or D as lexical head. That alternative captures the shared projection while retaining the primary-category boundary. The choice then returns to the membership argument: why should systematic nominal projection warrant inclusion for pronouns but require cross-category licensing for determinatives? The differences that motivate the determinative subcategory remain available under either description.

The D-noun analysis extends an established superordinate category to capture that common profile. Its justification combines the existing grounds for nounhood with the structural comparison; it doesn't rest on counting category names. A separate-D account could still be preferable if the primary boundary captured enough additional grammatical generalizations to offset the shared projection. The modifier contrast below supplies a concrete case to weigh.

A grammar with Hudson's nested classification can use the same permissions and projection rules. Holding those rules fixed, an added pronoun category between Noun and determinative leaves the fragment's judgments unchanged. Agreement on these judgments leaves the broader pronoun category open; it doesn't establish equivalence between the full analyses.

8.3 EXISTING RESTRICTIONS, ADDITIONAL COSTS AND CONSEQUENCES

The comparison starts with the restrictions already present in the grammar. Common nouns, proper nouns and pronouns already differ in determination and permitted modifiers (Table 3). Preserving those conditions is no additional cost of including determinatives. Likewise, the separate-D grammar already restricts adverbial modification and independent use within D. Moving those restrictions inside Noun doesn't create them.

The proposal changes the scope of one broader generalization. A ban on internal AdvP premodifiers can no longer be stated for Noun as a whole, because *hardly any* and *almost every* now contain noun heads. The restriction has to distinguish determinatives from the other noun subcategories. This is the consequence of the modifier contrast in Payne et al. (2010, pp. 40–42); the nounhood argument can't simply ignore it.

The proposal trades that primary-category formulation for shared nominal projection and a reduced phrase-type inventory in Det function. It preserves the determinative modifier profile explicitly, as the fragment shows. I favour this division because the nominal constructions recur across the subcategory, while the different dependent inventories remain describable where the lexical distinctions already lie. The auxiliary-as-verb precedent illustrates the same kind of separation between a shared category and specialized syntax; the nominal evidence supplies the justification here.

Cardinals illustrate a consequence of broadening Noun. Reynolds (2026) distinguishes determinative uses such as *ten men*, proper-noun uses such as *Room 101*, and common-noun uses such as *tens of pens*. Under the D-noun analysis, these uses fall within one superordinate category, with their differences retained at the subcategory and construction levels. This recasts the cardinal alternation without eliminating it. The argument doesn't extend to ordinals, which that study analyses as adjectives, or turn complex numeral phrases into single lexemes.

Approximative *or so* supplies a smaller constructional comparison: *fifteen or so minutes* and *ready by Tuesday or so*. CGEL identifies the numerical pattern as coordination (Huddleston & Pullum, 2002, 431, n. 47). The idiom spans cardinal and naming expressions in these constructed examples. Its dependence on a relevant scale, here quantity or time, limits its value as a category test. It is compatible with the broader nominal analysis without independently establishing it.

The shared-Det analysis would lose its claimed economy if determinative-headed and genitive NPs required different projection rules after their independently motivated feature restrictions were held fixed. Such a result would favour retaining the separate phrase types. The present fragment demonstrates a shared analysis; lower overall description length and advantages for learning or processing require further comparison.

9 CONCLUSION

I argue for determinative as a fourth noun subcategory in English. CGEL already admits pronouns within Noun on the basis of their phrase functions despite differences in inflection and dependents. Determinatives show the same kind of relation between systematic nominal uses and a distinctive internal profile. The case for inclusion follows that established standard and develops it through independent uses, partitives and modification.

Ordinary headedness gives the simple independent cases the nominal structure already needed elsewhere. Determinatives retain their lexical identity, and the articles retain their paradigmatic membership with independent use restricted. Predicative and modifier differences remain explicit. The analysis also removes the DP/NP phrase-type disjunction within determiner function, preserving feature selection and PP determiners. The cost is a narrower scope for some generalizations previously stated for Noun as a whole.

The corpus and matrix analyses establish the empirical scope of the comparison. They support attested nominal uses and distinguish coded determinative and pronoun profiles without fixing taxonomic rank. Coordinate subcategories preserve that local distinction within the existing nominal architecture; additional shared syntactic generalizations could favour Hudson's nesting. The central proposal is to extend to determinatives the nounhood that the framework already grants to other grammatically distinctive subcategories.

DATA AND ANALYSIS MATERIALS

The accompanying analysis/ directory contains the feature matrices, provenance records, scripts, generated tables and CGELBank concordance. The corpus inventory records the full source commit and file checksums. Analyses used R 4.6.1 and energy 1.7-12; environment details and the seed schedule accompany the outputs.

ACKNOWLEDGEMENTS. For the September 2026 revision, GPT-6 (Astra), Claude Opus 5, Claude Haiku 4.5 and GLM-5.3-Flash assisted drafting, source retrieval, script development or critical review; GPT-5.6 (Sol) checked numerical outputs. The accompanying materials record the tools and their uses. Responsibility for the analysis is mine.

A REPLICATION DETAILS

A.1 CORPUS INVENTORY

The four gold datasets come from revision d0a2c2d8c522 of the [CGELBank repository](#). The accompanying data record the full commit identifier and file checksums. Trial material, one-off examples and duplicate versions from the annotation study are excluded. Multiword lexical nodes count once. Overt source errors remain, with the corpus’s correction information retained.

For each D node, extraction follows Head relations upwards to the first non-Head relation, identifying the local function of its projection. The resulting counts are Det (297), Mod (18), Det–Head (65), Marker (1), Flat (4) and Coordinate (2). The concordance records each local phrase, its nearest containing NP and that NP’s function, and the source sentence.

The quantifier attestations in (2) have the sentence identifiers reviews-083459-0002 (a) and newsgroup-groups.google.com_INTPunderground_b2c62e87877e4a22_ENG_20050906_165900-0074 (b). Both resolve in the accompanying concordance.

A.2 FEATURE MATRIX AND SENSITIVITY CHECKS

The article by Reynolds (2021b) and the LingBuzz description of its matrix report 232 features, but the public file contains 155 (Reynolds, 2021a). The reanalysis preserves that file with its checksum and compares it with a recovered local 232-feature working matrix. The working matrix isn’t authenticated as the published input. The public file reproduces the published DISCO decomposition: between-group component 30.58286, within-group component 356.41607 and total 386.99893, giving $F = 11.670$ to the reported precision.

DISCO and k-groups use Euclidean distances between unscaled binary rows: the square root of the number of feature mismatches. Columns receive equal weight, so correlated diagnostics affect the geometry. DISCO uses CGEL’s determinative/pronoun partition. Runs with 999 permutations and seed 20260907 give $p = .001$ across the representations in Table 7, the minimum attainable value. The observations are coded word forms; the tests concern separation within this inventory.

The published k-groups code records a single random start and no seed. After removing the name column, it drops the first feature again during clustering. The reanalysis therefore tests both the public 155-feature input and that 154-feature implementation. For each representation, 100 single-start fits use seeds 1–100 and the published limit of ten iterations. A separate fit uses 100 starts and a limit of 100 iterations, selecting the best objective – the clustering criterion being minimized – among those starts.

Table 7: Exploratory sensitivity of the matrix analysis. The range is agreement out of 138 across 100 single-start fits. The last column is agreement for the best-objective fit among a separate set of 100 starts, not the maximum agreement observed. All displayed DISCO runs give $p = .001$ with 999 permutations.

Representation	Features	DISCO F	Range	Best objective
Public matrix	155	11.670	75–132	125/138
Without word-component columns	105	12.654	75–131	131/138
Syntactic columns	50	9.682	69–133	120/138
Syntactic, four labels removed	46	7.192	69–117	97/138

Cluster labels are oriented after fitting to maximize agreement with *CGEL*’s classification. Eight public-matrix single-start fits reproduce the published count of 129 matches; the 100-start fit yields 125. The 154-feature implementation also varies across starts. Selecting the best clustering objective doesn’t select the closest match to *CGEL*’s labels. Reducing the feature set can increase agreement in the fit selected by that objective, but the increase doesn’t independently support the taxonomy: the feature representation has changed.

Removing 50 word-component columns changes best-objective agreement to 131/138. The 50 syntactic columns yield 120/138; removing four explicit analysis labels yields 97/138. Those labels concern fused determiner-head function, partitive head function, subject-determiner function and coordination with non-fused determiners. This is a limited sensitivity check: the remaining judgments still reflect the descriptive framework. Complete scripts, feature changes, seed schedules and outputs accompany the paper.
